STUDIES RELATED TO WILDERNESS

Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral resource potential. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Trigo Mountains Wilderness Study Area, La Paz County, Arizona.

INTRODUCTION

In 1986 and 1987, the U.S. Geological Survey conducted a reconnaissance geochemical survey of the Trigo Mountains Wilderness Study Area, La Paz County, Arizona.

The Trigo Mountains Wilderness Study Area comprises about 47 mi² (29,895 acres) in the southwest corner of La Paz County, Arizona, and lies approximately 25 mi. north of Yuma, Arizona (fig. 1). Primary access to the study area is from the south by an unimproved dirt road running north from Martinez Lake, which is accessible by paved road from U.S. highway 95. Much of the area is inaccessible except by foot or helicopter.

Much of the study area is underlain by Tertiary volcanic rocks, primarily consisting of andesite and dacite lava flows and intrusions, but also including smaller amounts of ash flow tuffs scattered throughout the region. Also present in the central and northern portions of the study area are outcrops of pre-Tertiary crystalline rocks and fanglomerates of probable Miocene age.

The topography is characterized by sharp, sawtooth ridges and narrow, steep walled canyons; all of the washes in the area, including the major ones, are ephemeral. The topographic relief in the study area is about 1,700 ft (520m) with a maximum elevation of 1,920 ft (585m). Plant cover and soil development is sparse on the rocky ridges, but the major washes may support relatively thick riparian woodland. The climate is arid (Lower Sonoran Life Zone).

METHODS OF STUDY

Sample Media

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits. Heavy-mineral-concentrate samples provide information about the chemistry of certain minerals in rock material eroded from the drainage basin upstream from each sample site. The selective concentration of minerals, many of which may be ore related, permits determination of some elements that are not easily detected in stream-sediment samples.

Analyses of unaltered or unmineralized rock samples provide background geochemical data for individual rock units. On the other hand, analyses of altered or mineralized rocks, where present, may provide useful geochemical information about the major and trace-element assemblages associated with a mineralizing system.

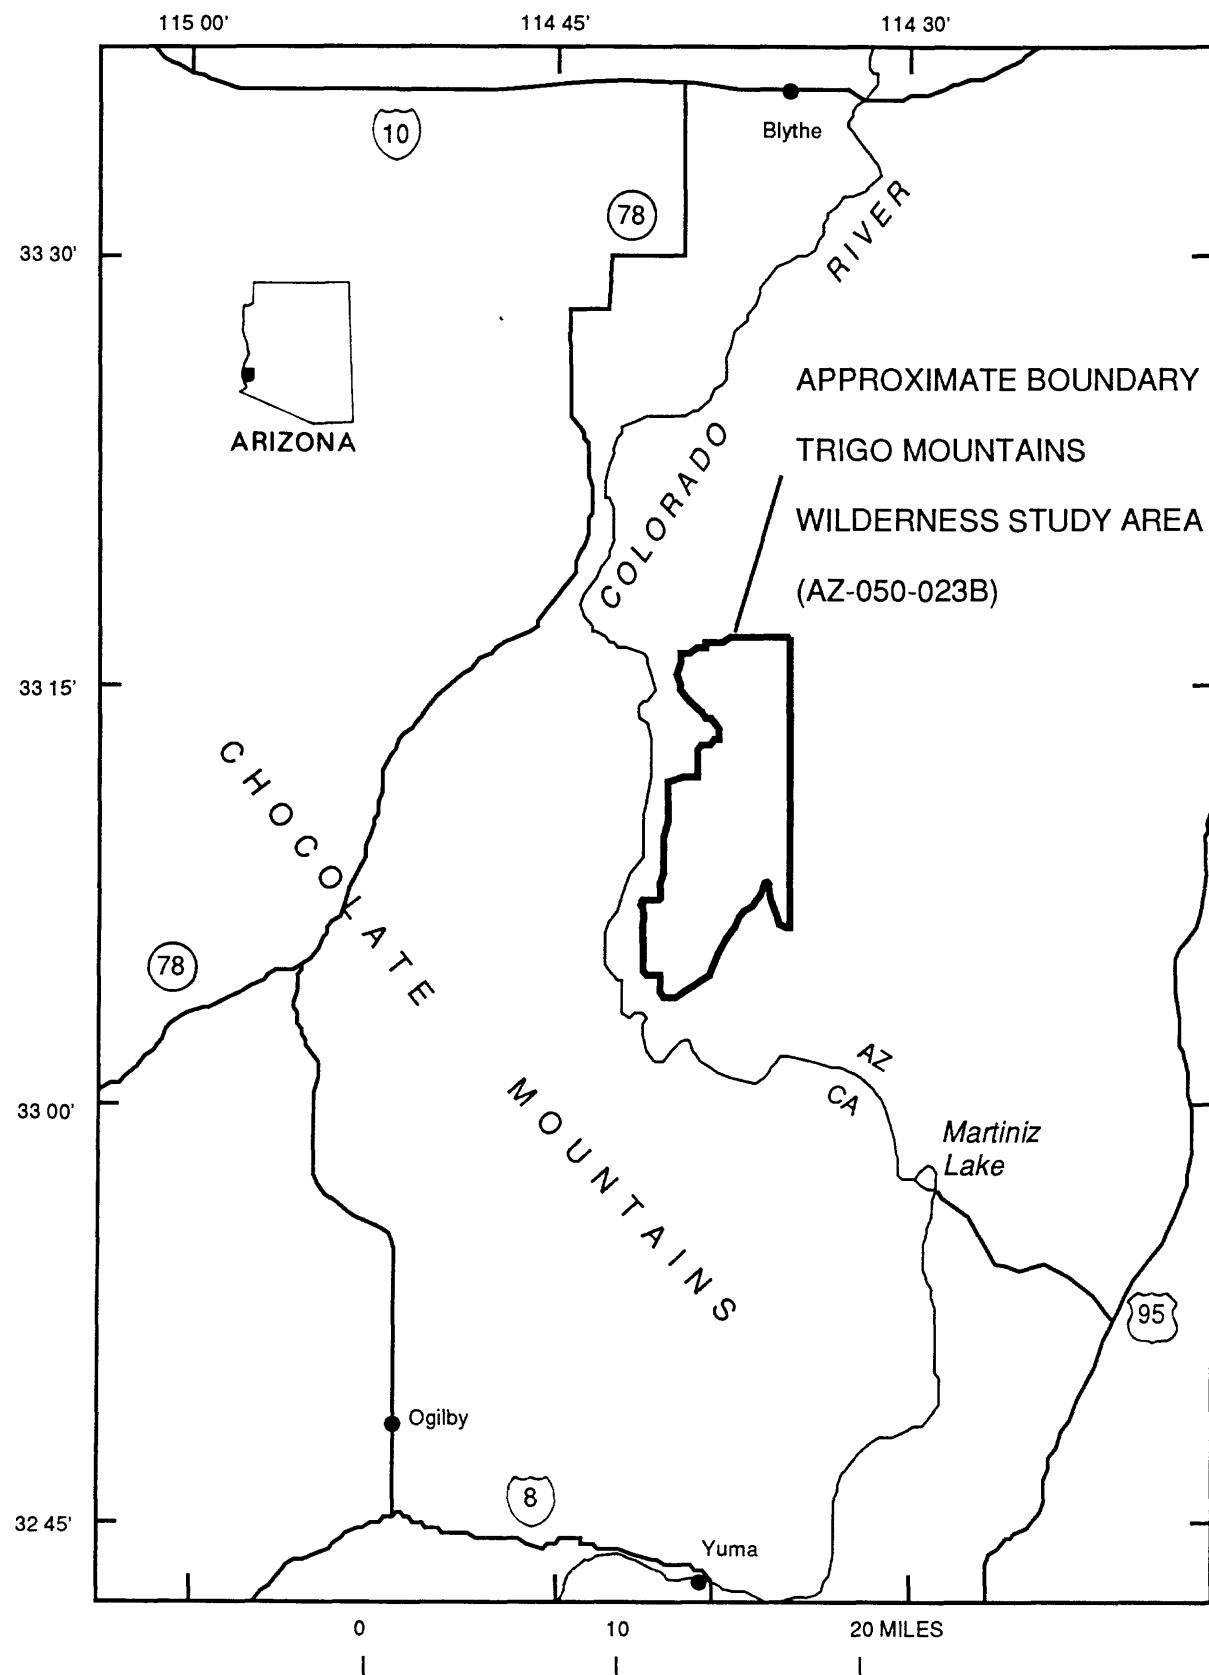

Figure 1. Index map of the location of the Trigo Mountains Wilderness Study Area, La Paz County, Arizona.

Sample Collection

Heavy-mineral-concentrate and stream-sediment samples were collected at 81 sites (plate 1). Rock samples were collected at 36 sites. Sampling density was about one sample site per 0.7 mi^2 for the stream sediments and heavy-mineral concentrates. The area of the drainage basins sampled ranged from 0.5 mi^2 to 4.0 mi^2 .

Stream-sediment samples

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic maps (scale = 1:24,000). Each sample was composited from several localities within an area that may extend as much as 20 ft from the site plotted on the map.

Heavy-mineral-concentrate samples

Heavy-mineral-concentrate samples were collected from the same active alluvium as the stream-sediment samples. Each bulk sample was screened with a 2.0-mm (10-mesh) screen to remove the coarse material. The less than 2.0-mm fraction was panned until most of the quartz, feldspar, organic material, and clay-sized material were removed.

Rock samples

Rock samples were collected from various types of occurrences in the vicinity of the plotted site location. Descriptions of rock samples are in table 6.

Sample Preparation

The stream-sediment samples were air dried, then sieved using 80-mesh (0.17-mm) stainless-steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

Samples that had been panned in the field were air dried and sieved to -35 mesh; bromoform (specific gravity 2.85) was used to remove the remaining quartz and feldspar. The resultant heavy-mineral-concentrate sample was separated into three fractions using a large electromagnet by placing the sample in contact with the face of the magnet (in this case a modified Frantz Isodynamic Separator). The most magnetic material, (removed at a setting of 0.25 ampere), primarily magnetite, was not analyzed. The second fraction, (removed at a setting of 1.75 ampere), largely ferromagnesian silicates and iron oxides, was saved for archival storage. The third fraction (the nonmagnetic material which may include the nonmagnetic ore minerals, zircon, sphene, etc.) was split using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogical analysis. These magnetic separates are the same separates that would be produced by using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.2 ampere to remove the magnetite and ilmenite, and a current of 0.6 ampere to split the remainder of the sample into paramagnetic and nonmagnetic fractions.

Rock samples were crushed and then pulverized to minus 0.15 mm with ceramic plates.

Sample Analysis

Spectrographic method

The stream-sediment, heavy-mineral-concentrate, and rock samples were analyzed for 31 elements using a semiquantitative, direct-current arc emission spectrographic method (Grimes and Marranzino, 1968). The elements analyzed and their lower limits of determination are listed in table 1. Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting interval at the 83 percent confidence level and plus or minus two reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements, iron, magnesium, calcium, and titanium, are given in weight percent; all others are given in parts per million (micrograms/gram). Analytical data for samples from the Trigo Mountains Wilderness Study Area are listed in tables 3, 4, and 5.

Chemical methods

Rock and stream-sediment samples were also analyzed by atomic absorption emission spectroscopy (AA) and inductively coupled plasma emission spectroscopy (ICP). Samples were analyzed for arsenic (As), antimony (Sb), bismuth (Bi), cadmium (Cd), and zinc (Zn) using AA and ICP, and for gold (Au) using flame AA. In addition, the rock samples were analyzed for mercury (Hg) using cold vapor AA, for Fluorine (F) using an ion selective electrode method and for Tungsten (W) using an instrumental colormetric method (cm). Limits of determination and references are listed in table 2.

Analytical results using these methods for stream-sediment and rock samples are listed in tables 3 and 5, respectively.

ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file called Rock Analysis Storage System (RASS). This data base contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

DESCRIPTION OF DATA TABLES

Tables 3-5 list the results of analyses for the stream-sediment, heavy-mineral-concentrate, and rock samples, respectively. For the three tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location map (plate 1). Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analyses; "aa" indicates atomic absorption analyses; "icp" indicates inductively coupled

plasma analyses; "cm" indicates colormetric analyses. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in tables 1 and 2. For emission spectrographic analyses, colormetric analyses of W, and AA analyses of Au, As, Sb, Bi, Cd, and Zn, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was observed but was below the lowest reporting value. For all ICP analyses and Hg analyses by AA, an "N" entered in the tables indicates that an element was below the lowest reporting value. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for in a sample, two dashes (--) were entered in tables 3-5 in place of an analytical value. Because of the formatting used in the computer program that produced tables 3-5, some of the elements listed in these tables (Fe, Mg, Ca, Ti, Ag, and Be) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.

ACKNOWLEDGMENTS

A number of our colleagues also participated in the preparation and analyses of these samples: preparation, Ted Sparks and John Unruh; and analyses, John Sharkey, Paul Briggs, Al Love, Olga Erlich, and P. Moore.

Table 6. Description of rock samples

Sample No.	Description
TM-01RA	Calcite/quartz vein: Black Rock Mine
TM-01RB	Gneiss: hanging wall Black Rock Mine
TM-01RC	Granite; stock work veins: footwall Black Rock Mine
TM-02R	Brown calcite vein: Red Cloud Mine
TM-02RA	(same as above)
TM-03R	Black calcite vein: Clip Mine
TM-04R	Black calcite vein: Princess Mine
TM-05RA	Black calcite vein: Dives Mine
TM-05RB	(same as above)
TM-05RC	Tuffaceous sediments: Dives Mine
TM-06RA	Calcite vein: Geronimo Mine South
TM-07R	Calcite vein: Geronimo Mine North
TM-18R	Silica banding in rhyolite
TM87001R	Fractured red volcanic rock with manganese coating
TM87002R	(same as above)
TM87003R	Quartz vein material
TM87004R	Mn/Fe oxide vein
TM87005R	Intermediate volcanic rock
TM87006R	Quartz vein
TM87007R	Unknown rock in intermediate volcanics
TM87008R	Clay-altered intermediate volcanic rock
TM87009R	Vuggy/silicified red volcanic rock
TM87010R	Volcanic rock
TM87011R	Quartz/calcite vein in TM87010R
TM87012R	Bleached volcanic rock
TM87013R	Fractured, bleached volcanic rock
TM87014R	Vein in silicified volcanic rock
TM87015R	Vein in volcanic breccia
TM87016R	Green chalcedony stockwork in volcanic rock
TM87017R	Red volcanic rock with Mn/Fe oxide staining
TM87018R	Gneiss: country rock, Hart Mine
TM87019R	Quartz vein with Fe/Mn oxides: Hart Mine
TM87020R	(same as above)
TM87021R	(same as above)
TM87022R	(same as above)
TM87023R	(same as above)
